1 LEFT HANDED COMPOSITE MEDIA

2 STATEMENT OF GOVERNMENT INTEREST

3 The invention in this application was made with the assistance of the
4 United States Government under grants from the NSF and DOE: NSF-DMR-96-
5 23949, NSF-DMR-9724535, DOE-DE-FG-03-93ER40793. The Government has
6 certain rights in this invention.

7 RELATED APPLICATIONS AND PRIORITY CLAIM

8 This application is related to prior provisional application serial no.
9 60/190,373 filed March 17, 2000. This application claims priority from that
10 provisional application under 35 U.S.C. §119.

11 FIELD OF THE INVENTION

12 The present invention is in the field of electromagnetic media and
13 devices.

14 BACKGROUND OF THE INVENTION

15 The behavior of electromagnetic radiation is altered when it interacts
16 with charged particles. Whether these charged particles are free, as in plasmas,
17 nearly free, as in conducting media, or restricted, as in insulating or
18 semiconducting media—the interaction between an electromagnetic field and
19 charged particles will result in a change in one or more of the properties of the
20 electromagnetic radiation. Because of this interaction, media and devices can be
21 produced that generate, detect, amplify, transmit, reflect, steer, or otherwise
22 control electromagnetic radiation for specific purposes. In addition to interacting
23 with charges, electromagnetic waves can also interact with the electron spin and/or

1 nuclear spin magnetic moments. This interaction can be used to make devices that
2 will control electromagnetic radiation. The properties of such media and devices
3 may further be changed or modulated by externally applied static or time-
4 dependent electric and/or magnetic fields. Other ways of producing changes in a
5 medium or device include varying temperature or applied pressure, or allowing
6 interactions with acoustic, ultrasonic, or additional electromagnetic waves (from
7 low frequencies up through the optical). Other changes could be effected by
8 introducing charged particle beams into the device or medium.

9 When electromagnetic radiation is incident on a medium composed
10 of a collection of either homogenous or heterogeneous scattering entities, the
11 medium is said to respond to the radiation, producing responding fields and
12 currents. The nature of this response at a given set of external or internal variables,
13 e.g., temperature and pressure, is determined by the composition, morphology and
14 geometry of the medium. The response may, in general, be quite complicated.
15 However, when the dimensions and spacing of the individual scattering elements
16 composing the medium are less than the wavelength of the incident radiation, the
17 responding fields and currents can be replaced by macroscopic averages, and the
18 medium treated as if continuous.

19 The result of this averaging process is to introduce averaged field
20 quantities for the electric and magnetic fields (**E** and **B**, respectively), as well as
21 the two additional averaged field quantities **H** and **D**. The four field vector
22 quantities are related at each frequency ω by the relations $\mathbf{B}=\mu(\omega)\mathbf{H}$ and $\mathbf{D}=\epsilon(\omega)\mathbf{E}$,
23 where $\epsilon(\omega)$ represents the medium parameter known as electrical permittivity, and
24 $\mu(\omega)$ represents the magnetic permeability. Wave propagation within a continuous
25 medium is characterized by the properties of the medium parameters. A
26 continuous medium is one whose electromagnetic properties can be characterized
27 by medium parameters that vary on a scale much larger than the dimension and
28 spacing of the constituent components that comprise the medium. At an interface
29 between a first continuous medium and a second continuous medium, wave

1 propagation is characterized by both the medium parameters of the first
2 continuous medium as well as the medium parameters of the second continuous
3 medium. The medium parameters may have further dependencies, such as on
4 frequency or direction of wave propagation, and may also exhibit nonlinear
5 response. There are limitations on the nature of $\mu(\omega)$ and $\epsilon(\omega)$ that must be
6 consistent with known physical laws; but many forms, such as tensor
7 representation, can occur in practice.

8 Naturally occurring media—those media either typically found in
9 nature, or that can be formed by known chemical synthesis—exhibit a broad, but
10 nonetheless limited, range of electromagnetic response. In particular, magnetic
11 effects are generally associated with inherently magnetic media, whose response
12 falls off rapidly at higher frequencies. It is thus difficult to find media with
13 significant permeability at RF and higher frequencies. Furthermore, media that
14 possess the important property of negative permeability are very rare, and have
15 only been observed under laboratory conditions in specialized experiments. In
16 contrast, many metals exhibit a negative permittivity at optical frequencies, but
17 other media exhibiting values of negative permittivity at optical or lower
18 frequencies (GHz, for example) are not readily available.

19 The averaging process that leads to the determination of medium
20 parameters in naturally occurring media, where the scattering entities are atoms
21 and molecules, can also be applied to *composite media*—media formed by
22 physically combining, mixing, or structuring two or more naturally occurring
23 media, such that the scale of spatial variation from one medium to the next is less
24 than the range of wavelengths of the electromagnetic radiation over which the
25 resulting medium is to be utilized. In many composite media, macroscopic
26 scattering elements replace microscopic atoms and molecules; yet the resulting
27 composite can be considered a continuous medium with respect to electromagnetic
28 radiation, so long as the average dimension and spacing are less than a
29 wavelength.

1 Nearly all practical naturally occurring and composite media have a
 2 permittivity and permeability both greater than zero, and generally equal to or
 3 greater than unity, at typical frequencies of interest. Such media are considered
 4 transparent if the inherent losses (imaginary parts of the permittivity or
 5 permeability) are sufficiently small. In transparent media, electromagnetic fields
 6 have the form of propagating electromagnetic waves, although the small amount
 7 of damping present may lead to absorption of a portion of the electromagnetic
 8 energy. If either the permittivity or the permeability is negative, but not both, then
 9 electromagnetic fields are non-propagating, and decay exponentially into the
 10 medium; such a medium is said to be opaque to incident radiation provided its
 11 thickness is greater than the characteristic exponential decay length. A familiar
 12 and pertinent example of a medium that can be either opaque or transparent
 13 depending on the frequency of excitation is given by a dilute plasma, which has a
 14 frequency dependent permittivity given by

$$15 \quad \varepsilon(\omega) = 1 - \frac{\omega_p^2}{\omega^2} \quad (1)$$

16 where ω_p is a parameter dependent on the density, charge, and mass of the charge
 17 carrier; this parameter is commonly known as the *plasma frequency*. For this
 18 illustration, μ is assumed to be unity for all frequencies. Below the plasma
 19 frequency, the permittivity is negative, and electromagnetic waves cannot
 20 propagate; the medium is opaque. Above the plasma frequency, the permittivity is
 21 positive, and electromagnetic waves can propagate through the medium. A
 22 familiar example of a dilute plasma is the earth's ionosphere, from which low-
 23 frequency radiation is reflected (when $\varepsilon(\omega) < 0$), but which transmits high-
 24 frequency radiation.

25 A wave propagating in the z-direction through a medium has the
 26 form $\exp[i(n(\omega)\omega z/c - i\omega t)]$, where i is the square root of -1 , and $n^2(\omega) = \varepsilon(\omega)\mu(\omega)$. A
 27 plane wave thus oscillates with time and position whenever the product $\varepsilon(\omega)\mu(\omega)$

1 is positive, and decays exponentially whenever the product $\epsilon(\omega)\mu(\omega)$ is negative.
 2 For transparent media, the product is positive and waves propagate.

3 Composite or naturally occurring media in which both $\epsilon(\omega)$ and $\mu(\omega)$
 4 are simultaneously negative have not been previously known. If both $\epsilon(\omega)$ and
 5 $\mu(\omega)$ are simultaneously negative, the product $\epsilon(\omega)\mu(\omega)$ is once again positive, and
 6 electromagnetic waves propagate. Thus, the square root is a real quantity, raising
 7 the question of whether electromagnetic waves can propagate in such a medium.
 8 Since only the product $\epsilon(\omega)\mu(\omega)$ enters into the form of a plane wave, it at first
 9 appears that there is no difference between a medium where both $\epsilon(\omega)$ and $\mu(\omega)$
 10 are simultaneously positive and a medium where both $\epsilon(\omega)$ and $\mu(\omega)$ are
 11 simultaneously negative.

12 In 1968, Veselago theoretically considered the properties of a
 13 medium in which both $\epsilon(\omega)$ and $\mu(\omega)$ were assumed to be simultaneously
 14 negative, by examining the solutions of Maxwell's equations. Even though
 15 Veselago noted that such a medium was nonexistent at the time, he pointed out
 16 that the existence of such media was not ruled out by Maxwell's equations, and
 17 presented a theoretical analysis of the manner in which electromagnetic waves
 18 would propagate. See, V.G. Veselago, *Soviet Physics USPEKHI* 10, 509 (1968).
 19 Veselago concluded that wave propagation in a medium with simultaneously
 20 negative $\epsilon(\omega)$ and $\mu(\omega)$ would exhibit remarkably different properties than media
 21 in which $\epsilon(\omega)$ and $\mu(\omega)$ are both positive.

22 In usual media, when both $\epsilon(\omega)$ and $\mu(\omega)$ are simultaneously
 23 positive, the direction of the energy flow, and the direction of the phase velocity
 24 (or wavevector \mathbf{k}) are in the same direction of $\mathbf{E} \times \mathbf{H}$. We term such a medium
 25 *right-handed*. When $\epsilon(\omega)$ and $\mu(\omega)$ are both negative, the direction of the phase
 26 velocity, given by $\mathbf{E} \times \mathbf{B}$, is opposite to the direction of energy flow, given by $\mathbf{E} \times \mathbf{H}$,
 27 as $\mathbf{H} = \mathbf{B}/\mu$. The directions of the field vectors \mathbf{E} and \mathbf{H} , and the direction of the
 28 propagation wavevector \mathbf{k} thus form a *left-handed* coordinate system, and

1 Veselago termed media with simultaneously negative $\epsilon(\omega)$ and $\mu(\omega)$ *left-handed*
2 *media* (LHM). Furthermore, Veselago suggested that the correct index-of-
3 refraction $n(\omega)$ to be used in the interpretation of Maxwell's equations should be
4 taken as the *negative* square root of the product $\epsilon(\omega)\mu(\omega)$, and thus that left-
5 handed media could be equivalently referred to as *negative refractive index media*.
6 The property of negative refractive index holds profound consequences for the
7 optics associated with left-handed media, and Veselago pointed out several
8 examples of how geometrical optics would be altered for lenses and other objects
9 composed of left-handed media. For example, a converging lens made of left-
10 handed medium would actually act as a diverging lens, and a diverging lens made
11 of left-handed medium would actually act as a converging lens. Also, the rays
12 emanating from a point source next to a planar slab of LHM could, given the
13 correct geometry and value of index-of-refraction, be brought to a focus on the
14 other side of the slab.

15 Veselago predicted a number of electromagnetic phenomena that
16 would occur in a LHM, including reversed refraction, reversal of the Doppler shift
17 and Cerenkov radiation, and the reversal of radiation pressure. These phenomena
18 were not demonstrable by Veselago due to the lack of a physical realization of a
19 left-handed medium.

20 **SUMMARY OF THE INVENTION**

21 The invention concerns composite media having simultaneous
22 negative effective permittivity and permeability over a common band of
23 frequencies. A composite medium of the invention combines media, which are
24 either themselves separately composite or continuous media, each having a
25 negative permittivity and a negative permeability over at least one common
26 frequency band. Various forms of separate composite and continuous media may
27 be relied upon in the invention.

1 In a preferred embodiment, one or both of the negative permeability
2 and negative permittivity media used in the composite medium of the invention
3 may be modulated via stimuli. Additionally, the medium or a portion thereof may
4 contain other media that have medium electromagnetic parameters that can be
5 modulated. The frequency position, bandwidth, and other properties of the left-
6 handed propagation band can then be altered from within or without, for example,
7 by an applied field or other stimulus. This modulation could result, for example, in
8 a composite medium that may be switched between left-handed and right-handed
9 properties, or between transparent (left-handed) and opaque (non-propagating)
10 over at least one band of frequencies. In addition, in a left-handed medium of the
11 invention it may be useful to introduce an intentional defect, e.g., a right handed
12 element or set of elements to act as a scattering “defect” within the medium. More
13 than one defect or arrays of defects may also be introduced.

14 A preferred composite media includes a periodic array of conducting
15 elements that can behave as a continuous medium for electromagnetic scattering
16 when the wavelength is sufficiently longer than both the element dimension and
17 lattice spacing. mediumThe preferred composite medium has an effective
18 permittivity $\epsilon_{\text{eff}}(\omega)$ and an effective permeability $\mu_{\text{eff}}(\omega)$ which are simultaneously
19 negative over a common band of frequencies.

20 BRIEF DESCRIPTION OF THE DRAWINGS

21 Other features, objects and advantages of the invention will be
22 apparent to those skilled in the art from the detailed description and figures, of
23 which:

24 FIG. 1 shows a preferred embodiment left-handed composite
25 medium of the invention;

26 FIG. 2(a) shows a split ring resonator of the type used in the FIG. 1
27 embodiment;

28 FIG. 2(b) is a resonance curve for the split ring resonator of FIG. 2;

1 FIG. 3(a) illustrates a dispersion curve for a split ring resonator for a
2 parallel polarization;

3 FIG. 3(b) illustrate a dispersion curve for a split ring resonator for a
4 perpendicular polarization;

5 FIG. 3(c) illustrates the effect of a conducting wire on the parallel
6 polarization of FIG. 3(a);

7 FIG. 3(d) illustrates the effect of a conducting wire on the
8 perpendicular polarization of FIG. 3(b);

9 FIG. 4 is a dispersion curve for a parallel polarization in medium of
10 the type shown in FIG. 1;

11 FIG. 5(a) illustrates a rectangular resonator;

12 FIG. 5(b) illustrates a single unit structure for an alternate
13 embodiment of the invention; and

14 FIG. 6 illustrates a "G" resonator.
15

16 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

17 While naturally occurring media have not been demonstrated that
18 can by themselves provide the appropriate medium properties necessary for a left-
19 handed medium, the invention combines either naturally occurring or composite
20 media in such a manner as to result in composite left-handed media. Composite
21 media have permeability and permittivity properties termed "effective." However,
22 the averaging procedure used to determine the effective medium parameters for a
23 composite structure is the same as that used to determine the medium parameters
24 for naturally occurring media. Thus, from an electromagnetic point of view, a
25 composite structure is equivalent to a continuous medium over a restricted band of
26 frequencies.

27 The present invention of a left handed composite medium requires
28 the combination of media that can give rise to simultaneously negative medium
29 parameters. Others have produced composite media having either a negative

1 permittivity or a negative permeability, but not both. These previously produced
 2 composite media may be used in the invention. Some specific examples are now
 3 discussed, while artisans will be able to practice the invention using other media
 4 through the guidance provided by the examples, the preferred embodiments and
 5 the additional descriptions found herein.

6 Composite media characterized by a frequency-dependent
 7 permittivity having the same form as a dilute plasma (Equation 1) were developed
 8 early on for a variety of scientific and practical applications (R. N. Bracewell,
 9 *Wireless Engineer*, 320, 1954; W. Rotman, *IRE Trans. Ant. Prop.*, **AP10**, 82,
 10 1962). In these media, which consisted of periodic arrangements of metal
 11 elements such as rods, wires, or spheres, the plasma frequency was shown to have
 12 a value related to the inductance per unit cell. Since the inductance is related to
 13 geometrical parameters, by varying the geometry of the scattering elements, the
 14 plasma frequency could be designed to have very low values, even in the
 15 microwave or radio wave region. This low plasma frequency is advantageous, as
 16 composite media with moderately negative values of the permittivity can be
 17 fabricated for applications at the low frequency. Practical applications of these
 18 composite enhanced permittivity media included microwave lenses, beam steering
 19 elements, and prisms.

20 In recent work (Pendry *et al.*, *Phys. Rev. Lett.*, **76**, 4773, 1996)
 21 Pendry *et al.* revisited, theoretically and numerically, a negative permittivity
 22 lattice of thin conducting wires, where the radius of a wire (*r*) was taken on the
 23 order of a micron, and the lattice spacing (*d*) on the order of several millimeters.
 24 Analysis showed that, for the parameters selected, the effective plasma frequency
 25 ω_p could be given by

$$26 \quad \omega_p^2 = 2\pi \frac{c^2}{d^2 \ln(d/r)} \quad (2)$$

1 where c is the speed of light in vacuum. In subsequent work, Pendry *et al.*
 2 provided experiments and more extensive calculations demonstrating that the thin
 3 wire structure was well characterized by the permittivity of Equation (1), with the
 4 plasma frequency as derived by Equation (2).

5 The purpose of utilizing wires thin in comparison to their spacing is
 6 to bring the plasma frequency below the diffraction frequency, which occurs when
 7 the wavelength is on the order of the lattice spacing. Other methods may also be
 8 used to reduce the plasma frequency. As an example, introducing loops into the
 9 wire lengths will reduce the plasma frequency since the plasma frequency is
 10 related inversely to the inductance per unit length in the structure (Smith *et al.*,
 11 *Appl. Phys. Lett.*, **75**, 10, 1999). If it is not necessary to distinguish the plasma
 12 frequency from the diffraction (or Bragg) frequency, the wires need not be thin in
 13 any sense.

14 Merkel (U.S. Patent No. 3,959,796) introduced a composite medium
 15 "...comprising a random distribution of inductively-loaded short dipoles for
 16 simulating the macroscopic electromagnetic properties of a simple Lorentz
 17 plasma." Merkel's structure exhibited a similar permittivity function as the thin
 18 wire structure. Pendry *et al.* (*J. Phys.: Condens. Matter*, **10**, 4785, 1998) showed
 19 that by breaking the electrical continuity of wires, capacitance is introduced into
 20 the structure, resulting in an electrical resonance occurring. The general form of
 21 the permittivity for an inductive structure in which electrical continuity is not
 22 maintained is then

$$23 \quad \varepsilon(\omega) = 1 - \frac{\omega_p^2}{\omega^2 - \omega_{e0}^2}. \quad (3)$$

24 As it is possible to design composite media that exhibit enhanced
 25 electric response to electromagnetic fields, it is also possible to design composite
 26 media that exhibit enhanced *magnetic* response to electromagnetic fields. While it
 27 is of course possible to employ inherently magnetic media for this purpose (i.e.,

1 media whose magnetic properties result from the spin rather than classical
2 currents), such media are best suited for lower or zero frequency applications, as
3 these effects tend to tail off with frequency. Also, the range of values for the
4 permeability corresponding to naturally occurring magnetic media (e.g.,
5 ferromagnets, ferrimagnets or antiferromagnets) is found empirically to be
6 typically limited to positive values. Furthermore, the presence of static magnetic
7 fields is often required, which can perturb the sample and, for example, potentially
8 make isotropic response difficult to obtain.

9 Because of the difficulties associated with inherently magnetic
10 media, it is convenient to utilize non-magnetic media to achieve an effective
11 magnetic response. Structures in which local currents are generated that flow so
12 as to produce *solenoidal* currents in response to applied electromagnetic fields, can
13 produce the same response as would occur in magnetic media, but at much higher
14 frequencies. Generally, any element that includes a non-continuous conducting
15 path nearly enclosing a finite area, and further introduces capacitance into the
16 circuit by some means, will have solenoidal currents induced when a time-varying
17 magnetic field is applied parallel to the axis of the circuit. We term such an
18 element a *solenoidal resonator*, as such an element will possess at least one
19 resonance at a frequency ω_{m0} determined by the introduced capacitance and the
20 inductance associated with the current path. Solenoidal currents are responsible
21 for the responding magnetic fields, and thus solenoidal resonators are equivalent to
22 magnetic scatterers. A simple example of a solenoidal resonator is ring of wire,
23 broken at some point so that the two ends come close but do not touch, and in
24 which capacitance has been increased by extending the ends to resemble a parallel
25 plate capacitor. A composite medium composed of solenoidal resonators, spaced
26 closely so that the resonators couple magnetically, exhibits an effective
27 permeability. Such a composite medium was described in the text by I. S.
28 Schelkunoff and H. T. Friis, *Antennas: Theory and Practice*, Ed. S. Sokolnikoff

1 (John Wiley & Sons, New York, 1952), in which the generic form of the
 2 permeability (in the absence of resistive losses) was derived as

3

$$\mu(\omega) = 1 - \frac{\omega_{mp}^2}{\omega^2 - \omega_{m0}^2} . \quad (4)$$

4 Provided that the resistive losses are low enough, Equation 4 indicates that a
 5 region of negative permeability should be obtainable, extending from ω_{m0} to
 6 $(\omega_{mp} + \omega_{m0})$.

7 In 1999, Pendry *et al.* revisited the concept of magnetic composite
 8 structures, and presented several methods by which capacitance could be
 9 conveniently introduced into solenoidal resonators to produce the magnetic
 10 response (Pendry *et al.*, *Magnetism from Conductors and Enhanced Nonlinear*
 11 *Phenomena*, IEEE Transactions on Microwave Theory and Techniques, Vol. 47,
 12 No. 11, pp. 2075-84, November 11, 1999; see also PCT application). Pendry *et al.*
 13 suggested two specific elements that would lead to composite magnetic media.
 14 The first was a two-dimensionally periodic array of “Swiss rolls,” or conducting
 15 sheets, infinite along one axis, and wound into rolls with insulation between each
 16 layer. The second was an array of double split rings, in which two concentric
 17 planar split rings formed the resonant elements. Pendry *et al.* proposed that the
 18 latter medium could be formed into two- and three-dimensionally isotropic
 19 structures, by increasing the number and orientation of double split rings within a
 20 unit cell.

21 Pendry *et al.* used an analytical effective medium theory to derive
 22 the form of the permeability for their composite structures. This theory indicated
 23 that the permeability should follow the form of Equation (4), which predicts very
 24 large positive values of the permeability at frequencies near but below the resonant
 25 frequency, and very large negative values of the permeability at frequencies near
 26 but just above the resonant frequency, ω_{m0} .

1 All such and similar composite media provide the possibility of use
2 in a composite left-handed medium of the invention. A continuous medium with
3 negative permeability is also possible to use. For example, although rare, negative
4 $\mu_{\text{eff}}(\omega)$ has also been shown to be possible in naturally occurring media when a
5 polariton resonance exists in the permeability, such as in MnF_2 and FeF_2 , or
6 certain insulating ferromagnets and antiferromagnets (D. L. Mills, E. Burstein,
7 *Rep. Prog. Phys.*, **37**, 817, 1974). Under the appropriate conditions of frequency
8 and applied magnetic field resonances associated with these media produce
9 negative values of the permeability. These and other forms of negative
10 permeability may be used in the invention, which is directed to combinations of
11 media, composite or continuous, to form a composite medium having
12 simultaneous negative permeability and permittivity over at least one band of
13 frequencies.

14 Artisans considering the above examples will appreciate that there
15 may be numerous ways in which to arrive at a medium in which one (but not both)
16 of the medium parameters have values less than zero, by using either a suitable
17 naturally occurring medium, or by fabricating composite medium. If a first
18 medium is shown or anticipated to have a region of negative permittivity, and a
19 second medium is shown or anticipated to have a region of negative permeability,
20 then the combination of the two said media may, but not necessarily, produce a
21 left-handed medium (LHM). It is possible, for example, that the two media might
22 interact in an undesired manner, such that the effective medium parameters of the
23 composite are not predicted by assuming the permittivity of the first medium and
24 the permeability of the second medium. It must be determined by either
25 simulation or experiment whether or not a medium composed of two distinct
26 media, one with negative permittivity and one with negative permeability,
27 possesses a left-handed propagation band. This can be accomplished, for example,
28 by careful transmission measurements on the composite sample, in which the
29 phase and amplitude of the transmitted and reflected waves are recorded as a

1 function of frequency, and used to determine the values of $\mu(\omega)'$, $\mu(\omega)''$, $\epsilon(\omega)'$,
2 and $\epsilon(\omega)''$ Since the permeability and permittivity are complex quantities, four
3 separate functions are required to completely specify the medium parameters as a
4 function of frequency. This type of test is commonly referred to in engineering
5 literature as an “S-parameters” test.

6 While an S-parameters test is a useful method of characterizing the
7 electromagnetic properties of a medium, a sufficient test to determine if the
8 combination of two media has resulted in a LHM is to measure the transmission of
9 electromagnetic waves through either medium separately, and the transmission of
10 electromagnetic waves through the composite. The transmission measurement
11 test is the preferred method for designing and characterizing an LHM.

12 If electromagnetic waves are incident on a sample composed of a
13 medium having a frequency band where either the permittivity or the permeability
14 is negative (but not both), the sample is opaque and the incident waves are rejected
15 from the sample leading to attenuation of the transmitted power. For a thick
16 enough sample, a transmission “stop band” will be apparent for frequency bands
17 where one of the medium parameters is negative.

18 If a new composite medium can be made where the negative
19 permittivity frequency band of the first medium has some overlap with the
20 negative permeability frequency band of the second medium, then a transmission
21 measurement through a thick sample should produce a transmission band in that
22 frequency band rather than the attenuation region corresponding to either medium
23 alone. If there is no transmission band present, then the combination of media will
24 have resulted in an undesired interaction, and the medium electromagnetic
25 parameters of the composite may not be easily related to the medium
26 electromagnetic parameters of either medium alone.

27 In order to best achieve a LHM, it is desirable to combine two media
28 together, the first having primarily an electric response to incident radiation and
29 the second having primarily a magnetic response to incident radiation. The

1 selected medium should have a frequency band where its medium electromagnetic
2 parameter is negative. An electric medium thus has a frequency band over which
3 the permittivity is negative, and a magnetic medium has a frequency band over
4 which the permeability is negative. In this manner, the two media are less likely
5 to produce undesired interactions when combined. The electromagnetic properties
6 of either the electric or the magnetic medium alone may be determined by
7 experiment or simulation, and may be purposefully designed to optimize
8 frequency location, bandwidth, dispersion characteristics and other figures of
9 merit where the dominant medium parameter is negative.

10 It will be appreciated that there are many naturally occurring or
11 composite media whose electric properties over a band of frequencies are best
12 characterized by a negative permittivity. It will also be appreciated that while they
13 are less obvious, there are also naturally occurring or composite media whose
14 magnetic properties over a band of frequencies can be best characterized by a
15 negative permeability. The combination of an electric medium and a magnetic
16 medium is capable, in principle, of yielding a LHM. The following set of
17 examples in no way exhausts the possibilities methods of creating LHMs, but
18 presents some practical implementations from which those skilled in the art will be
19 able to understand and use LHM through the teaching of the invention.

20 The LHM can be built up as a physically constructed composite, the
21 combination of an electric medium and a magnetic medium. The electric and
22 magnetic media, considered separately, are most simply visualized as comprised
23 of identical *units* (or *cells*). Within at least some of the units are located one or
24 more elements designed to contribute to a negative permittivity or a negative
25 permeability. Each element may represent either a portion of continuous medium,
26 plasma, or a scattering object. The size of the unit is preferably significantly
27 smaller than the wavelength of the applied electromagnetic radiation, as it is for
28 these dimensions that bulk effective medium parameters are most properly
29 applied. The LHM can then be understood as a combination of units, some units

1 being composed of the electric medium, and other units being composed of the
2 magnetic medium. This model is conceptual, as the units may be entirely
3 composed of a continuous medium, in which case the division into units is
4 arbitrary. In the resulting medium, the new composite unit may encompass the
5 element, or the medium, of the electric medium as well as the element, or the
6 medium, of the magnetic medium.

7 When the media are combined, it is reasonable to assume that there
8 will be other media present that facilitate the assembly of the composite, but do
9 not necessarily contribute toward the left-handed electromagnetic properties of the
10 composite. These media or other elements are termed the “substrate.”

11 In one preferred embodiment, the electric and magnetic units are
12 periodically distributed, although within each unit the effective permittivity or
13 permeability may be anisotropic, resulting in a medium in which the left-handed
14 frequency band occurs only for one or two propagation directions. The spatial
15 distributions of the units may include fractal, pseudorandom, random, or many
16 other types. Either one or both of the negative permeability and negative
17 permittivity media used in the composite medium of the invention may be
18 modulated via external or internal stimulus. Thus, the composite medium may be
19 switched between left-handed and right-handed properties, or between transparent
20 (left-handed) and opaque (non-propagating) over at least one band of frequencies.
21 Such switching is the extreme case, with lesser modulations to change values of
22 permittivity or permeability within the positive and negative range also being
23 useful. Another possibility is the use of a substrate which responds to external or
24 internal stimulus. A substrate that includes a piezoelectric material may serve to
25 modulate the physical size of the substrate by a locally applied electric field. A
26 substrate or element component incorporating magnetostrictive material may serve
27 also to modulate the physical size of the substrate by an applied magnetic field.
28 Additionally, the medium or a portion thereof may contain other media that have
29 medium electromagnetic parameters that can be modulated. For example, a

1 portion of the medium may be modulated by diverse resonance excitation such as
2 NMR, EPR, CESR, AFR, FMR, and paraelectric resonance. Additionally, media
3 used may be photomodulated. The frequency position, bandwidth, and other
4 properties of the left-handed propagation band can then be altered, for example, by
5 an applied field or other stimulus.

6 One purpose of modulation includes the goal of achieving control or
7 stabilization, or tuning sample properties. Methods of varying or controlling
8 temperature, for example, could be to utilize heating currents in the wires
9 themselves. Application of additional RF, or even optical frequencies, could
10 introduce temperature changes in parts or all of the sample.

11 One method for establishing or modulating permittivity is to use a
12 gas plasma as the medium. The plasma frequency of Equation 1 corresponds to a
13 resonance of the electrons in the plasma. In addition, it is possible to have a
14 second resonant response of a plasma containing ions which are free to move.
15 Ions, having a much larger mass than electrons, have a much lower plasma
16 frequency. Through control of the current, applied electric field or applied
17 magnetic field or gas density, the permittivity of a gas plasma in its value,
18 including a change from negative to positive value. The gas plasma may be
19 contained in tubes or sheets. A change of the magnetic permeability of a medium
20 can occur from media comprised of a ferromagnetic, ferromagnetic, or anti-
21 ferromagnetic medium. Such changes could be accomplished by an applied
22 magnetic field.

23 In addition, in a left-handed medium of the invention it may be
24 useful to introduce an intentional defect comprised of any configuration of any
25 material which differs from that of the surrounding medium. An example of a
26 defect within a left-handed medium could be a portion of negative permittivity, or
27 negative permeability, or right handed material less than a wavelength. More than
28 one defect or arrays of defects may also be introduced.

090412-20260

1 A left-handed medium of the invention may include a continuous
2 medium, or a fabricated element designed to give rise to a composite medium
3 when all such units are considered as a collective medium. These elements may
4 be fabricated by any of the many forms of machining, electroless- or electro-
5 plating, direct write process, lithography, multi-media deposition build-up, self-
6 organized assembly, and so forth. Examples of elements include, but are not
7 limited to, a length of conducting wire, a wire with a loop (or loops) along its
8 length, a coil of wire, or several wires or wires with loops. Further examples
9 include those based on solenoidal resonators. A practical example of a solenoidal
10 resonator is provided in I. S. Schelkunoff and H. T. Friis, *Antennas: Theory and*
11 *Practice*, Ed. S. Sokolnikoff (John Wiley & Sons, New York, 1952). Further
12 examples were recently introduced by Pendry *et al.* (IEEE Transactions on
13 Microwave Theory and Techniques, Vol. 47, No. 11, pp. 2075-84, November 11,
14 1999), and include the “G” structure, double split ring resonators, Swiss roll
15 structures, and planar spirals.

16 The conducting elements described in the preceding paragraph are
17 not restricted solely to metal conductors. Indeed it may be advantageous to use
18 diverse methods of fabrication discussed to deposit conducting elements in the
19 desired geometries, sizes and position, where the conducting material may be
20 composed of optically transparent, such as indium-tin oxide, or other types of
21 “wires” such as conducting polymers, carbon nanotubes, and biomolecular
22 polymers such as DNA, which conduct charge to a sufficient degree.

23 As describe above, it may be necessary to suspend or support the
24 elements that are desired to produce the left-handed properties on other media
25 termed the substrate. These media will then enter geometrically and
26 electromagnetically into the unit, even though they may not be required to produce
27 the left-handed properties. Examples of substrates include, but are not limited to,
28 plastics; fiberglass; semiconducting media; insulating media, such as quartz
29 (SiO_2), sapphire (Al_2O_3), or glass; or other composites. Substrates may also act as

1 containers for elements comprised of liquids, gases, and/or plasmas. Substrates
2 may further include other gasses, vacuum, plastics and epoxies, neutral gas
3 plasmas, insulating chemicals, compounds or composite media. In addition to the
4 substrates and elements, the remaining space may be partially or totally filled with
5 a choice of host media. These host media may be chosen for a variety of functions
6 and functionality, including providing absorption and dissipation of the
7 electromagnetic waves, strength of the medium, to make a purposeful choice of
8 design for the permittivity or permeability, or as a means of introducing other
9 functional components, such as capacitors and inductors, or other active
10 components, such as amplifiers, oscillators, antennas, or the like.

11 A preferred embodiment of the invention utilizes a medium of
12 double split ring resonators to form a magnetic medium (having a frequency band
13 with negative permeability) and a composite wire medium (having a frequency
14 band with negative permittivity). This embodiment forms the primary basis for
15 exemplifying the ideal of the invention, which is a combination of a first
16 composite or continuous medium having an effective permeability for a frequency
17 band which is negative, with a second composite or continuous medium having an
18 effective permittivity over a frequency band which is negative, and wherein the
19 two frequencies regions have a region of overlap. The preferred embodiment
20 system illustrates necessary principles concerning production of a medium of the
21 invention. The exemplary embodiment presented here in FIG. 1 is anisotropic to
22 simplify the analysis, having left-handed properties in only one direction of
23 propagation.

24 In the preferred embodiment shown in FIG. 1, two composite media
25 are combined to form a LHM. The negative permeability medium of the invention
26 is formed from an array of solenoidal resonators 10, each solenoidal resonator 10
27 having a dimension much smaller than the wavelength over which it responds
28 resonantly. The preferred embodiment of FIG. 1 uses Pendry's double split ring
29 resonators medium (SRRs) to create a negative permeability medium. The

1 negative permittivity medium results from the interwoven array of conducting
 2 wires 12. A supporting structure of dielectric medium 14 acts as a substrate to
 3 arrange the wires and SRRs 10.

4 A single SRR 10 is shown in FIG. 2(a). The SRR includes
 5 concentric split rings 16 and 18 of nonmagnetic (copper) medium. The lattice
 6 parameter is $a=8.1$ mm, $c=0.8$ mm, $d=0.2$ mm and $r=1.5$ mm. A time varying
 7 magnetic field applied parallel to the axis of the rings induces currents that,
 8 depending on the frequency and the resonant properties of the unit, produce a
 9 magnetic field that may either oppose or enhance the incident field. Calculations
 10 on the modes associated with SRRs 10 show that the associated magnetic field
 11 pattern from an SRR largely resembles that associated with a magnetic dipole.
 12 The splits in the rings of the SRR allow the element to be resonant at wavelengths
 13 much larger than the diameter of the rings. The purpose of the second split ring 18,
 14 inside and whose split is oriented opposite to the first ring 16, is to increase the
 15 capacitance in the element, concentrating electric field within the small gap region
 16 between the rings and lowering the resonant frequency considerably. The
 17 individual SRR shown in FIG. 2(a) has its resonance peak at 4.845 GHz. The
 18 corresponding resonance curve is shown in FIG. 2(b). Because the dimensions of
 19 an element are so much smaller than the free space wavelength, the radiative
 20 losses are small, and the Q is relatively large (>600 in the case above, as found by
 21 microwave measurements as well as numerical simulation).

22 By combining the split ring resonators into a periodic medium such
 23 that there is sufficient (magnetic) coupling between the resonators, unique
 24 properties emerge from the composite. In particular, because these resonators
 25 respond to the incident magnetic field, the composite medium can be viewed as
 26 having an effective permeability, $\mu_{\text{eff}}(\omega)$. The general form of the permeability has
 27 been presented above (Equation 4); however, the geometry-specific form of the
 28 effective permeability was studied by Pendry et al., where the following
 29 expression was derived:

$$1 \quad \mu_{\text{eff}} = 1 - \frac{\frac{\pi r^2}{a^2}}{1 - \frac{3\ell}{\pi^2 \mu_0 \omega^2 C r^3} + i \frac{2\ell\rho}{\omega r \mu_0}} = 1 - \frac{F\omega^2}{\omega^2 - \omega_0^2 + i\omega\Gamma} \quad (5)$$

2 Here, ρ is the resistance per unit length of the rings measured around the
 3 circumference, ω is the frequency of incident radiation, l is the distance between
 4 layers, r , and a , the dimensions indicated FIG. 2(a), F is the fractional area of the
 5 unit cell occupied by the interior of the split ring, Γ is the dissipation factor, and C
 6 is the capacitance associated with the gaps between the rings. The expressions for
 7 ω_0 and Γ can be found by comparing the terms in Equation 5. Since the Q-factor
 8 of an individual SRR used in the experiments was measured to be greater than
 9 600. Thus, effects due to damping are relatively small.

10 While the expression for the capacitance of the SRR may be
 11 complicated in the actual structure, the general form of the resonant permeability
 12 shown in Equation 5 leads to a generic dispersion curve. There is a region of
 13 propagation from zero frequency up to a lower band edge, followed by a gap, and
 14 then an upper pass band. There is a symmetry, however, between the dielectric and
 15 permeability functions in the dispersion relation $\omega = \frac{ck}{\sqrt{\epsilon(\omega)\mu(\omega)}}$, where c is the
 16 velocity of light in vacuum. The gap corresponds to a region where either
 17 $\epsilon_{\text{eff}}(\omega)$ or $\mu_{\text{eff}}(\omega)$ is negative. If it is assumed that there is a resonance in $\mu_{\text{eff}}(\omega)$ as
 18 suggested by Equation 5, and that $\epsilon_{\text{eff}}(\omega)$ is positive and slowly varying, the
 19 presence of a gap in the dispersion relation implies a region of negative $\mu_{\text{eff}}(\omega)$.
 20 One cannot uniquely determine via only a simple measurement, or even the
 21 measurement of the dispersion relation itself, whether the gap is due to a
 22 resonance in the $\epsilon_{\text{eff}}(\omega)$ with reasonably constant $\mu_{\text{eff}}(\omega)$, or due to a resonance in
 23 $\mu_{\text{eff}}(\omega)$ with reasonably constant $\epsilon_{\text{eff}}(\omega)$.

1 Using MAFIA Release 4.0, a commercial finite-difference code,
2 dispersion curves were generated for the periodic infinite metallic structure
3 consisting of the split ring resonators of FIG. 1. The dispersion curves are shown
4 in FIGs. 3(a)-3(d). There are two incident polarizations of interest: magnetic field
5 polarized along the split ring axes (H_{\parallel} , FIG. 3(a) inset), and perpendicular to the
6 split ring axes (H_{\perp} , FIG. 3(b) inset). In both cases, the electric field is in the plane
7 of the rings. As shown by the curves in FIGs. 3(a) and 3(b), a band gap is found in
8 either case, although the H_{\parallel} gap of FIG. 3(a) can be interpreted as being due to a
9 negative $\mu_{\text{eff}}(\omega)$, and the H_{\perp} gap of FIG. 3(b) can be interpreted as being due to a
10 negative $\epsilon_{\text{eff}}(\omega)$. The negative permeability region for the H_{\parallel} modes begins at 4.2
11 GHz and ends at 4.6 GHz, spanning a band of about 400 MHz. Not evident from
12 the FIG. 3(b), but consistent with the model indicated in Equation 5,
13 $\mu_{\text{eff}}(\omega)$ switches to a large negative value at the lower band edge, decreasing in
14 magnitude (but still negative) for increasing frequency through the gap. At the
15 upper band edge, $\mu_{\text{eff}}(\omega) = 0$, and a longitudinal mode exists (not shown), identified
16 as the magnetic plasmon mode by Pendry et al. For the dielectric gap shown in
17 FIG. 3(b), the same behavior is observed, but with the roles of $\epsilon_{\text{eff}}(\omega)$ and
18 $\mu_{\text{eff}}(\omega)$ reversed.

19 The insertion of a conducting wire into each unit alters the
20 permittivity of the surrounding medium. The conducting wire is shown in FIG.
21 3(c) and 3(d). The combination of a conducting wire medium and a SRR medium
22 provides the basis for the exemplary preferred left handed medium of the
23 invention shown in FIG. 1. Since the wire structure alone is known to contribute a
24 negative effective permittivity from ω_c to ω_p , the consideration of the wire also
25 helps distinguish whether the band gaps illustrated in FIGs. 3(a) and 3(b) are due
26 to either the $\mu_{\text{eff}}(\omega)$ or $\epsilon_{\text{eff}}(\omega)$ of the SRR being negative.

1 In a 2-D medium composed of periodically placed conducting posts
 2 like those shown in FIGs. 3(c) and 3(d), there is a single gap in propagation up to a
 3 cutoff frequency, ω_p , for modes with the electric field polarized along the axis of
 4 the posts. This onset of propagation has been identified by others with an
 5 effective plasma frequency dependent on the wire radius and spacing, with the
 6 effective dielectric function following the form $\epsilon_{\text{eff}}(\omega) = 1 - \frac{\omega_p^2}{\omega^2}$. A reduction in
 7 ω_p can be achieved by restricting the current density to thin wires, which also
 8 increases the self-inductance per unit length, L . When the conductivity of the
 9 wires is large, the plasma frequency has been shown by others to have the general
 10 form $\omega_p = (d^2 L \epsilon_0)^{-1/2}$, and a wire structure can be shown to have a ω_p at
 11 microwave or lower frequencies. Combining the SRR medium having a frequency
 12 band gap due to a negative permeability, with a conducting wire medium in
 13 accordance with the invention produces a resultant left-handed medium in the
 14 region where both $\mu_{\text{eff}}(\omega)$ and $\epsilon_{\text{eff}}(\omega)$ have negative values simultaneously.

15 Numerical simulations were carried out that modeled a medium of
 16 parallel posts of radius 0.4mm interleaved with a SRR medium. Electromagnetic
 17 modes were considered in which the electric field was polarized parallel to the
 18 axes of the posts, as shown in the inset of FIG. 3(c). The results of these
 19 simulations are shown as dashed lines in FIGs. 3(c) and 3(d). For the wire medium
 20 alone, a gap extends from zero frequency to ω_p , at 13 GHz. When the wire
 21 medium is added to the SRR medium, such that the posts are placed symmetrically
 22 between SRRs, for the H_{\parallel} case a pass band (the dashed line in FIG. 3(c) occurs
 23 within the previously forbidden band of the SRR dispersion curves of FIG. 3(a).
 24 The occurrence of this pass band within a previously forbidden region indicates
 25 that the negative $\epsilon_{\text{eff}}(\omega)$ for this region has combined with the negative $\mu_{\text{eff}}(\omega)$ to
 26 allow propagation, as predicted by the simulations.

1 By combining the ideal frequency dependence for the wire medium
 2 with Equation 5 for the permeability of SRRs, the following expression for the
 3 dispersion relation of the combined medium can be derived:

$$4 k^2 = \frac{(\omega^2 - \omega_p^2)}{c^2} \frac{(\omega^2 - \omega_b^2)}{(\omega^2 - \omega_0^2)} \quad (6)$$

5 Equation (6) shows that the range of the propagation band (k real) extends from
 6 ω_0 to $\omega_b = \omega_0 / \sqrt{1-F}$. This was formerly the region of the gap of the SRR
 7 structure in the absence of the posts. The dispersion relation leads to a band with
 8 negative group velocity throughout, and a bandwidth that is independent of the
 9 plasma frequency for the condition $\omega_p > \omega_b$.

10 The behavior of the magnetic gap can be contrasted with that
 11 occurring for the H_\perp case, which has been identified as a dielectric gap. Because H
 12 is parallel to the plane of the SRR, magnetic effects are small, and $\mu_{\text{eff}}(\omega)$ is small,
 13 positive, and slowly varying. As shown in FIG. 3(d), a pass band (dashed line)
 14 again occurs, but now outside of the forbidden region, and within a narrow range
 15 that ends abruptly at the band edge of the lowest propagation band. The pass band
 16 in this case occurs where the effective dielectric function of the split rings exceeds
 17 the negative dielectric function of the wire medium. As the dispersion curves
 18 calculated do not include losses, there will always be a range of pass-band
 19 frequencies, however narrow, when the resonant dielectric medium of split rings is
 20 combined with the negative dielectric medium of wires. Once again, the behavior
 21 of the dielectric gap can be described by an approximate dispersion relation:

$$22 k^2 \square \frac{(\omega^2 - \omega_p^2)}{c^2} \frac{(\omega^2 - \omega_f^2)}{(\omega^2 - \omega_0^2)} \quad (7)$$

23 where $\omega_f^2 = \omega_0^2 \omega_p^2 / (\omega_0^2 + \omega_p^2)$. The derivation of Equation 7 neglects the difference
 24 between ω_0 and ω_b , as ω_b does not play an essential role here, and assumes

1 $\omega_p \gg \omega_0$. The propagation band in this case extends from ω_f to ω_0 , with a
 2 bandwidth strongly dependent on the plasma frequency. As the plasma frequency
 3 is lowered, the lower edge of the propagation band lowers, increasing the overall
 4 bandwidth. The group velocity of this band is always positive. Both Equations 6
 5 and 7 neglect medium losses (i.e., $\Gamma=0$). The contrast between the two
 6 propagation bands in the H_{\parallel} and H_{\perp} cases illustrates the difference between the
 7 magnetic and dielectric responses of the SRR.

8 SRR's of the form of FIG. 1 were fabricated using a commercially
 9 available printed circuit board. In order to test the results of the simulations,
 10 square arrays of SRRs were constructed with a lattice spacing of 8.0 mm between
 11 elements. As the magnetic flux generated by the SRR is required to return within
 12 the unit cell, the fractional area F is the critical parameter for the enhancement of
 13 the permeability.

14 Microwave scattering experiments were performed on the fabricated
 15 SRR medium, and the combined SRR/metal wire medium. In order to ease the
 16 required size of the structure, A two-dimensional microwave scattering chamber,
 17 described by Smith *et al.*, *J. Opt. Soc. Am. B*, **10**, 314 (1993) was utilized. The
 18 scattering chamber is made out of aluminum, with a grid pattern of holes in the top
 19 plate to allow source and probe antenna coupling. Microwave absorber medium
 20 placed around the periphery of the chamber minimized reflection back into the
 21 scattering region.

22 For the H_{\parallel} polarization, 17 rows of SRRs were utilized in the H
 23 direction, (8 elements deep in the propagation direction) oriented as in FIG. 3(a)
 24 (inset). FIG. 4 shows the results of transmission experiments on split rings alone
 25 (solid curve), and split rings with posts placed uniformly between (dashed curve).
 26 The square array of metal posts alone had a cutoff frequency of 12 GHz; the
 27 region of negative permittivity below this frequency, where the medium was
 28 opaque, attenuated the transmitted power to below the noise floor of the

1 microwave detector (−52 dBm). When the SRR medium was added to the wire
2 array, a pass band occurred, consistent with the propagation region indicated by
3 the simulation (FIG. 3(c)).

4 Many other geometries are possible. Generally, the geometry of the
5 solenoidal resonator must enclose significant amount of magnetic flux to ensure
6 generation of solenodial current. Control or modulation of the properties or
7 functionality of a LHM of the invention can be effected by placing nonlinear
8 media within the split ring gaps, due to the large electric fields built up within the
9 gaps. Similarly, magnetic media can be placed inside the SRRs at optimum
10 positions to be effected by the strong local magnetic fields. The ability of the
11 LHM to effect the propagation of an electromagnetic wave will depend upon the
12 incident field amplitude, direction, polarization and length of time of application.
13 More than one source of electromagnetic field may be introduced in order to serve
14 as a stimulus to drive a region of nonlinear medium. Superconducting media, if
15 used for the conductive medium forming the resonator units, may reduce
16 microwave attenuation length due to lower losses.

17 Another exemplary geometry is shown in FIGs. 5(a) and 5(b). FIG.
18 5(b) shows a left-handed unit replicable in any direction to form a left hand
19 medium of the invention having a left-handed propagation frequency bands for
20 waves traveling in any direction in a plane perpendicular to the wires, operable
21 over frequencies in the 8-12 GHz band (or X-band). This geometry is a two-
22 dimensional left-handed medium, having left-handed propagation bands that occur
23 for only two directions of propagation. By utilizing three orthogonal sets of split
24 rings and corresponding wires extending in all three dimensions, a three-
25 dimensional left-handed medium can be formed. Each unit 20 in the medium is
26 formed from a dielectric medium 22, e.g., fiberglass circuit board, with vertically
27 arranged solenoidal resonators 24 (see FIG. 5(a)) on a surface of the circuit board.
28 The resonators 24 are concentric and split, and are loosely referred to as split rings
29 despite their rectangular shape. Conducting stripes 26 are formed on the reverse

1 side of the circuit board, oriented so as to be centered with the split rings. Viewed
2 from the perspective of a particular resonator in a unit, an individual wire is in line
3 with the gaps of the resonators but in a plane behind the resonators.

4 The wires 26, which create negative permittivity, need not be
5 electrically connected to that of the next unit. The effect of this is to create a
6 propagation band that starts from zero frequency to a cut off, where a frequency
7 band gap occurs that has negative permittivity. The frequency band gap
8 corresponding to the split ring resonators is placed to overlap with this first gap to
9 create a region of simultaneously negative permittivity and permeability. In the
10 isotropic two-dimensional structure shown in FIG. 5(b), a left-handed propagation
11 band occurs along the (1,0), (0,1) and (1,1) directions of incidence. Experiments
12 and simulations have shown overlapping transmission bands for the incident
13 microwave radiation.

14 Another exemplary resonator which meets the general criteria of
15 enclosing significant amount of magnetic flux to ensure generation of solenodial
16 current is shown in FIG. 6. FIG. 6 is the “G” resonator. The “G” resonator uses a
17 single ring, as opposed to having a smaller ring enclosed by a larger ring as in the
18 other exemplary embodiments. Nonetheless, the resonator of FIG. 6 provides the
19 basis for another alternate composite negative permeability structure.

20 Utilizing the methods and the media discussed, one may design and
21 fabricate a composite material in which the value of the refractive index may be
22 varied from zero, over an appreciable range of values. A particularly useful value
23 is -1 . If the permittivity and permeability of the medium both have a value of -1 ,
24 the medium has the unusual property that any shape or extent of the medium will
25 have greatly reduced reflection for frequencies at which those values are achieved.

26 A composite sample formed from the combination of a sheet of a
27 given thickness of a left-handed composite medium of the invention and a sheet of
28 a given thickness of a right-handed medium may be designed to reduce overall
29 reflected power. This reduction comes about because the phase advance in a LHM

1 is opposite to that of a RHM, so that the composite may produce a lowered net
2 total phase advance. A composite sample of this type which results in a
3 significantly reduced net total phase advance of the transmitted wave is termed a
4 conjugate sample.

5 As an example, a lossless RHM sheets of medium having a given
6 index n_1 and a given impedance z_1 when combined with a LHM slab of equal
7 length and equivalent impedance $z_2=z_1$ and equal magnitude but opposite sign of
8 the refractive index ($n_2=-n_1$) will produce a combination sample with no reflection.
9 This will be true at any frequency for which the previously described equalities
10 hold, and for all angles of incidence. Matching a LHM and RHM structure over a
11 broad frequency band requires LHM and RHM structures with equal impedances
12 and indices-of-refraction properties equal in magnitude but opposite in sign over a
13 given frequency band. The LHM is termed the conjugate match to the RHM.

14 In many cases it will be desirable to simultaneously reduce both the
15 overall reflected power and the transmitted power from a conjugate sample. This
16 may be accomplished by introducing adiabatically a means of absorbing the
17 electromagnetic radiation. As an example, absorption could be introduced by
18 increasing the resistivity of the components of the LHM adiabatically in the
19 direction of wave propagation. Additionally, absorbing materials may be introduced
20 into the substrate medium or host medium.

21 As described above, Veselago concluded that the Cerenkov radiation
22 from a charged beam traveling through a left-handed medium at speeds greater
23 than the phase velocity of electromagnetic waves within the medium would be
24 reversed, so as to propagate in a direction opposite to that of the charged beam.
25 Certain devices, known as backward wave oscillators, produce radiation from
26 charged beams. These devices must make use of particular structures periodic on
27 the order of the wavelength of the generated electromagnetic radiation in order to
28 create a backward traveling wave that interacts with the forward moving particle
29 bunches. A LHM, in conjunction with suitably reflecting components, can act as

1 an intrinsic backward wave oscillator, as charged particle bunches introduced will
2 generate backward waves in a manner similar to periodic structures in RHM.

3 While specific embodiments of the present invention have been
4 shown and described, it should be understood that other modifications,
5 substitutions and alternatives are apparent to one of ordinary skill in the art. Such
6 modifications, substitutions and alternatives can be made without departing from
7 the spirit and scope of the invention, which should be determined from the
8 appended claims.

9 Various features of the invention are set forth in the appended
10 claims.
